

Computer Vision Group Prof. Daniel Cremers

Visual Navigation for Flying Robots Place Recognition, ICP, and Dense Reconstruction

Dr. Jürgen Sturm

Exercise Sheet 5

- Prepare mid-term presentation
- Proposed structure: 3 slides
 - Remind people who you are and what you are doing (can be same slide as last time)
 - 2. Your work/achievements so far (video is a plus)
 - **3**. Your plans for the next two weeks
- Hand in slides before July 3, 10am

Agenda for Today

Localization

- Visual place recognition
- Scan matching and Iterative Closest Point
- Mapping with known poses (3D reconstruction)
 - Occupancy grids
 - Octtrees
 - Signed distance field
 - Meshing

Remember: Loop Closures

 Use loop-closures to minimize the drift / minimize the error over all constraints

How can we detect loop closures efficiently?

How can we detect loop closures efficiently?

1. Compare with all previous images O(n) (not efficient)

How can we detect loop closures efficiently?

2. Use motion model and covariance to limit search radius (metric approach)

How can we detect loop closures efficiently?

3. Appearance-based place recognition (using bag of words)

Appearance-based Place Recognition

Appearance can help to recover the pose estimate where metric approaches might fail

Analogy to Document Retrieval

Of all the sensory impressions proceeding to the brain, the visual experiences are the dominant ones. Our perception of the world around us is based essentially s that reach the brain from e it was sensory, brain, thought the vitted point by visual, perception, the cerebra retinal, cerebral cortex, upon w Throug eye, cell, optical now kn nerve, image perceptic Hubel, Wiesel more comp the visual in the various cell lave Hubel and Wiesel have been e that the message about the image fall the retina undergoes a step-wise analy system of nerve cells stored in columns. system each cell has its specific function responsible for a specific detail in the patter the retinal image.

China is forecasting a trade surplus of \$90bn (£51bn) to \$100bn this year, a threefold increase on 2004's \$32bn. The Commerce Ministry said the surplus would be created by a predicted 30% \$750bn. compared y 660bn. China, trade, The figur US. surplus, commerce, which h are unfairly exports, imports, US, vuan. yuan, bank, domestic, says th foreign, increase, governo needed t trade, value so more god increased the the dollar by 2.1% in T trade within a narrow band, but the US the yuan to be allowed to trade freely. ver, Beijing has made it clear that it will take ρ and tread carefully before allowing the rise further in value.

Object/Scene Recognition

 Analogy to documents: The content can be inferred from the frequency of visual words

object

bag of visual words

Bag of Visual Words

Visual words = (independent) features

face

features

Bag of Visual Words

- Visual words = (independent) features
- Construct a dictionary of representative words

dictionary of visual words (codebook)

Bag of Visual Words

- Visual words = (independent) features
- Construct a dictionary of representative words
- Represent the image based on a histogram of word occurrences (bag)

Each detected feature is assigned to the closest entry in the codebook

Overview

feature detection and extraction (e.g., SIFT, ...)

codewords dictionary

image representation
(histogram of word
occurrences)

Learning the Dictionary

$\longrightarrow \left[\blacksquare \right] \left[\blacksquare \right] \left[\blacksquare \right] \left[\blacksquare \right] \cdots$

descriptor vectors
(e.g., SIFT, SURF, ...)

example patch 16

Learning the Dictionary

Learning the Dictionary

Visual Navigation for Flying Robots

Learning the Visual Vocabulary

feature extraction & clustering

Example Image Representation

 Build the histogram by assigning each detected feature to the closest entry in the codebook

Object/Scene Recognition

- Compare histogram of new scene with those of known scenes, e.g., using
 - simple histogram intersection

$$score(\mathbf{p}, \mathbf{q}) = \sum \min(p_i, q_i)$$

- naïve Bayes
- more advanced statistical methods

21

Visual Navigation for Flying Robots

Example: FAB-MAP

[Cummins and Newman, 2008]

Timing Performance

- Inference: 25 ms for 100k locations
- SURF detection + quantization: 483 ms

Summary: Bag of Words

[Fei-Fei and Perona, 2005; Nister and Stewenius, 2006]

- Compact representation of content
- Highly efficient and scalable
- Requires training of a dictionary
- Insensitive to viewpoint changes/image deformations (inherited from feature descriptor)

Laser-based Motion Estimation

- So far, we looked at motion estimation (and place recognition) from visual sensors
- Today, we cover motion estimation from range sensors
 - Laser scanner (laser range finder, ultrasound)
 - Depth cameras (time-of-flight, Kinect ...)

Laser Scanner

Measures angles and distances to closest obstacles

$$\mathbf{z} = (\theta_1, z_1, \dots, \theta_n, z_n) \in \mathbb{R}^{2n}$$

- Alternative representation: 2D point set (cloud) $\mathbf{z} = (x_1, y_1, \dots, x_n, y_n)^\top \in \mathbb{R}^{2n}$
- Probabilistic sensor model $p(z \mid x)$

Laser-based Motion Estimation

How can we best align two laser scans?

Laser-based Motion Estimation

How can we best align two laser scans?

- Exhaustive search
- Feature extraction (lines, corners, ...)
- Iterative minimization (ICP)

Exhaustive Search

Convolve first scan with sensor model

 Sweep second scan over likelihood map, compute correlation and select best pose

Example: Exhaustive Search [Olson, '09]

- Multi-resolution correlative scan matching
- Real-time by using GPU
- Remember: SE(2) has 3 DOFs

Does Exhaustive Search Generalize To 3D As Well?

Iterative Closest Point (ICP)

Given: Two corresponding point sets (clouds)

$$P = \{\mathbf{p}_1, \dots, \mathbf{p}_n\}$$
$$Q = \{\mathbf{q}_1, \dots, \mathbf{q}_n\}$$

 Wanted: Translation t and rotation R that minimize the sum of the squared error

$$E(R, \mathbf{t}) = \frac{1}{n} \sum_{i=1}^{n} ||\mathbf{p}_i - R\mathbf{q}_i - \mathbf{t}||^2$$

where p_i and q_i are corresponding points

Known Correspondences

Note: If the correct correspondences are known, both rotation and translation can be calculated in **closed form**.

Known Correspondences

Idea: The center of mass of both point sets has to match

$$\bar{\mathbf{p}} = \frac{1}{n} \sum_{i} \mathbf{p}_{i} \qquad \bar{\mathbf{q}} = \frac{1}{n} \sum_{i} \mathbf{q}_{i}$$

- Subtract the corresponding center of mass from every point
- Afterwards, the point sets are zero-centered,
 i.e., we only need to recover the rotation...

Known Correspondences

Decompose the matrix

$$W = \sum_{i} (\mathbf{p}_{i} - \bar{\mathbf{p}}) (\mathbf{q}_{i} - \bar{\mathbf{q}})^{\top} = USV^{\top}$$

using singular value decomposition (SVD)

Theorem

If rank W = 3, the optimal solution of E(R, t) is unique and given by

$$R = UV^{\top}$$

$$\mathbf{t} = \bar{\mathbf{p}} - R\bar{\mathbf{q}}$$

(for proof, see http://hss.ulb.uni-bonn.de/2006/0912/0912.pdf, p.34/35)

Unknown Correspondences

 If the correct correspondences are not known, it is generally impossible to determine the optimal transformation in one step

- Algorithm: Iterate until convergence
 - Find correspondences
 - Solve for R,t
- Converges if starting position is "close enough"

Example: ICP

Visual Navigation for Flying Robots

ICP Variants

Many variants on all stages of ICP have been proposed:

- Selecting and weighting source points
- Finding corresponding points
- Rejecting certain (outlier) correspondences
- Choosing an error metric
- Minimization

Performance Criteria

- Various aspects of performance
 - Speed
 - Stability (local minima)
 - Tolerance w.r.t. noise and/or outliers
 - Basin of convergence (maximum initial misalignment)
- Choice depends on data and application

Selecting Source Points

- Use all points
- Uniform sub-sampling
- Random sampling
- Feature-based sampling
- Normal-space sampling
 - Ensure that samples have normals distributed as uniformly as possible

Spatially Uniform Sampling

- Density of points usually depends on the distance to the sensor → no uniform distribution
- Can lead to a bias in ICP

Feature-based Sampling

Detect interest points (same as with images)

- Decrease the number of correspondences
- Increase efficiency and accuracy
- Requires pre-processing

3D Scan (~200.000 Points) Visual Navigation for Flying Robots

Extracted Features (~5.000 Points)

Dr. Jürgen Sturm, Computer Vision Group, TUM

Normal-Space Sampling

Uniform sampling

Normal-space sampling

Example: Normal-Space Sampling

Normal-space sampling can help on mostlysmooth areas with sparse features

Random sampling

Normal-space sampling

Visual Navigation for Flying Robots

Selection and Weighting

- Selection is a form of (binary) weighting
- Instead of re-sampling one can also use weighting
- Weighting strategy depends on the data
- Pre-processing / run-time trade-off

Finding Correspondences

Has greatest effect on convergence and speed

- Closest point
- Normal shooting
- Closest compatible point
- Projection
- Speed-up using kd-trees (or oct-trees)

Closest Point Matching

- Find closest point in the other point set
- Distance threshold

 Closest-point matching generally stable, but slow and requires pre-processing

Normal Shooting

Project along normal, intersect other mesh

 Slightly better than closest point for smooth meshes, worse for noisy or complex meshes

Closest Compatible Point

- Can improve effectiveness of both the previous variants by only matching to compatible points
- Compatibility based on normals, colors, ...
- In the limit, degenerates to feature matching

Speeding Up Correspondence Search

Finding closest point is most expensive stage of the ICP algorithm

- Build index for one point set (kd-tree)
- Use simpler algorithm (e.g., projection-based matching)

Projection-based Matching

- Slightly worse performance per iteration
- Each iteration is one to two orders of magnitude faster than closest-point
- Requires point-to-plane error metric

Error Metrics

- Point-to-point
- Point-to-plane lets flat regions slide along each other

 Generalized ICP: Assign individual covariance to each data point [Segal, 2009]

Visual Navigation for Flying Robots

Minimization

- Only point-to-point metric has closed form solution(s)
- Other error metrics require non-linear minimization methods
 - Which non-linear minimization methods do you remember?
 - Which robust error metrics do you remember?

Robust Error Metrics

Example: Real-Time ICP on Range Images

[Rusinkiewicz and Levoy, 2001]

- Real-time scan alignment
- Range images from structure light system (projector and camera, temporal coding)

ICP: Summary

- ICP is a powerful algorithm for calculating the displacement between point clouds
- The overall speed depends most on the choice of matching algorithm
- ICP is (in general) only locally optimal → can get stuck in local minima

Agenda for Today

Localization

- Visual place recognition
- Scan matching and Iterative Closest Point

Mapping with known poses (3D reconstruction)

- Occupancy grids
- Octtrees
- Signed distance field
- Meshing

Occupancy Grid

Idea:

- Represent the map m using a grid
- Each cell is either free or occupied

$$\mathbf{m} = (m_1, \ldots, m_n) \in \{\text{empty}, \text{occ}\}^n$$

Robot maintains a belief $Bel(\mathbf{m})$ on map state

Goal: Estimate the belief from sensor observations

$$Bel(\mathbf{m}) = P(\mathbf{m} \mid \mathbf{z}_1, \dots, \mathbf{z}_t)$$

Occupancy Grid - Assumptions

- Map is static
- Cells have binary state (empty or occupied)
- All cells are independent of each other

- As a result, each cell m_i can be estimated independently from the sensor observations
- Will also drop index i (for the moment)

Mapping

Goal: Estimate

$$Bel(m) = P(m \mid z_1, \dots, z_n)$$

How can this be computed?

Binary Bayes Filter

Goal: Estimate

$$Bel(m) = P(m \mid z_1, \ldots, z_n)$$

- How can this be computed?
- E.g., using the Bayes Filter from Lecture 3

$$P(m \mid z_{1:t}) = \left(1 + \frac{1 - P(m \mid z_t)}{P(m \mid z_t)} \frac{1 - P(m \mid z_{1:t-1})}{P(m \mid z_{1:t-1})} \frac{P(m)}{1 - P(m)}\right)^{-1}$$

Binary Bayes Filter

- Prior probability that cell is occupied P(m) (often 0.5)
- Inverse sensor model P(m | z_t) is specific to the sensor used for mapping
- The log-odds representation can be used to increase speed and numerical stability

$$L(x) := \log \frac{p(x)}{p(\neg x)} = \log \frac{p(x)}{1 - p(x)}$$

Binary Bayes Filter using Log-Odds

In each time step, compute

inverse previous belief sensor model map prior $L(m \mid z_{1:t}) = L(m \mid z_{1:t-1}) + L(m \mid z_t) + L(m)$

When needed, compute current belief as

$$Bel_t(m) = 1 - \frac{1}{1 + \exp L(m \mid z_{1:t})}$$

Clamping Update Policy

- Often, the world is not "fully" static
- Consider an appearing/disappearing obstacle
- To change the state of a cell, the filter needs as many positive (negative) observations
- Idea: Clamp the beliefs to min/max values

 $L'(m \mid z_{1:t}) = \max(\min(L(m \mid z_{1:t}), l_{\max}), l_{\min})$

Sensor Model

 For the Bayes filter, we need the inverse sensor model

 $p(m \mid z)$

- Let's consider an ultrasound sensor
 - Located at (0,0)
 - Measures distance of 2.5m
 - How does the inverse sensor model look like?

Typical Sensor Model for Ultrasound

 Combination of a linear function (in xdirection) and a Gaussian (in y-direction)

Question: What about a laser scanner?

Example: Updating the Occupancy Grid

+	X	+	X	+	$\langle \Sigma \rangle$		
+	$\langle \Sigma \rangle$	+		+	X		
+		+		+	<u>(1</u>)		
+	<u>_</u>	+	2	+	.25)		
+	.25)	+	.20	+	<u>(1</u>)		
+	(A)	+	20	+	20	\rightarrow	T

Visual Navigation for Flying Robots

Resulting Map

Note: The maximum likelihood map is obtained by clipping the occupancy grid map at a threshold of 0.5

Memory Consumption

- Consider we want to map a building with 40x40m at a resolution of 0.05cm
- How much memory do we need?

Memory Consumption

- Consider we want to map a building with 40x40m at a resolution of 0.05cm
- How much memory do we need?

$$\left(\frac{40}{0.05}\right)^2 = 640.000 \text{ cells} = 4.88 \text{mb}$$

And for 3D?

$$\left(\frac{40}{0.05}\right)^3 = 512.000.000 \text{ cells} = 3.8\text{gb}$$

And what about a whole city?

Visual Navigation for Flying Robots

Map Representation by Octtrees

- Tree-based data structure
- Recursive subdivision of space into octants
- Volumes can be allocated as needed
- Multi-resolution

Example: OctoMap

[Wurm et al., 2011]

Freiburg, building 79
 44 x 18 x 3 m³, 0.05m resolution, 0.7mb on disk

[Wurm et al., 2011]

Freiburg computer science campus
 292 x 167 x 28 m³, 0.2m resolution, 2mb on disk

Signed Distance Field (SDF)

[Curless and Levoy, 1996]

- Idea: Instead of representing the cell occupancy, represent the distance of each cell to the surface
- Occupancy grid maps: explicit representation

Signed Distance Field (SDF)

[Curless and Levoy, 1996]

Algorithm:

- **1**. Estimate the signed distance field
- Extract the surface using interpolation (surface is located at zero-crossing)

Weighting Function

 Weight each observation according to its confidence

 Weight can additionally be influenced by other modalities (reflectance values, ...)

Visual Navigation for Flying Robots

Data Fusion

- Each voxel cell x in the SDF stores two values
 - Weighted sum of signed distances $D_t(\mathbf{x})$
 - Sum of all weights $W_t(\mathbf{x})$
- When new range image arrives, update every voxel cell according to

$$D_{t+1}(\mathbf{x}) = D_t(\mathbf{x}) + w_{t+1}(\mathbf{x})d_{t+1}(\mathbf{x})$$
$$W_{t+1}(\mathbf{x}) = W_t(\mathbf{x}) + w_{t+1}(\mathbf{x})$$

Two Nice Properties

Noise cancels out over multiple measurements

 Zero-crossing can be extracted at sub-voxel accuracy (least squares estimate)

1D Example:
$$x^* = \frac{\sum D_t(x)x}{\sum W_t(x)x}$$

SDF Example

A cross section through a 3D signed distance function of a real scene

Surface with cross-section

SDF

SDF Fusion

Visualizing Signed Distance Fields

Common approaches to iso surface extraction:

- Ray casting (GPU, fast)
 For each camera pixel, shoot a ray and search for zero crossing
- Poligonization (CPU, slow)
 E.g., using the marching cubes algorithm Advantage: outputs triangle mesh

Ray Casting

- For each camera pixel, shoot a ray and search for the first zero crossing in the SDF
- Value in the SDF can be used to skip along when far from surface

Ray Casting

- Interpolation reduces artifacts
- Close to surface, gradient represents the surface normal

Marching Cubes

First in 2D, marching squares:

- Evaluate each cell separately
- Check which edges are inside/outside
- Generate triangles according to lookup table
- Locate vertices using least squares

Marching Cubes

KinectFusion

[Newcombe et al., 2011]

- Projective ICP with point-to-plane metric
- Truncated signed distance function (TSDF)
- Ray Casting

Lessons Learned Today

- How to quickly recognize previously seen places
- How to align point clouds
- How to estimate occupancy maps
- How to reconstruct triangle meshes at subvoxel accuracy
