# **Variational Methods**

Variational methods are a class of optimization methods. They are popular because they allow to solve many problems in a mathematically transparent manner. Instead of implementing a heuristic sequence of processing steps (as was commonly done in the 1980's), one clarifies beforehand what properties an 'optimal' solution should have.

Variational methods are particularly popular for infinite-dimensional problems and spatially continuous representations.

Particular applications are:

- Image denoising and image restoration
- Image segmentation
- Motion estimation and optical flow
- Spatially dense multiple view reconstruction
- <span id="page-2-0"></span>• Tracking

### **Advantages of Variational Methods**

Variational methods have many advantages over heuristic multi-step approaches (such as the Canny edge detector):

- A mathematical analysis of the considered cost function allows to make statements on the existence and uniqueness of solutions.
- Approaches with multiple processing steps are difficult to modify. All steps rely on the input from a previous step. Exchanging one module by another typically requires to re-engineer the entire processing pipeline.
- Variational methods make all modeling assumptions transparent, there are no hidden assumptions.
- Variational methods typically have fewer tuning parameters. In addition, the effect of respective parameters is clear.
- Variational methods are easily fused one simply adds respective energies / cost functions.

# **Example: Variational Image Smoothing**

Let  $f: \Omega \to \mathbb{R}$  be a grayvalue input image on the domain  $\Omega \subset \mathbb{R}^2.$  We assume that the observed image arises by some 'true' image corrupted by additive noise. We are interested in a denoised version *u* of the input image *f*.

The approximation *u* should fulfill two properties:

- It should be as similar as possible to *f*.
- It should be spatially smooth (i.e. 'noise-free').

Both of these criteria can be entered in a cost function of the form

 $E(u) = E_{data}(u, f) + E_{smoothness}(u)$ 

The first term measures the similarity of *f* and *u*. The second one measures the smoothness of the (hypothetical) function *u*.

<span id="page-4-0"></span>Most variational approaches have the above form. They merely differ in the specific form of the data (similarity) term and the regularity (or smoothness) term.

### **Example: Variational Image Smoothing**

For denoising a grayvalue image  $f: \Omega \subset \mathbb{R}^2 \to \mathbb{R}$ , specific examples of data and smoothness term are:

$$
E_{\text{data}}(u, f) = \int_{\Omega} (u(x) - f(x))^2 dx,
$$

and

$$
E_{\textit{smoothness}}(u) = \int_{\Omega} |\nabla u(x)|^2 dx,
$$

where  $\nabla=(\partial/\partial{\pmb{x}},\partial/\partial{\pmb{y}})^\top$  denotes the spatial gradient.

Minimizing the weighted sum of data and smoothness term

$$
E(u) = \int (u(x) - f(x))^2 dx + \lambda \int |\nabla u(x)|^2 dx, \quad \lambda > 0,
$$

leads to a smooth approximation  $u : \Omega \to \mathbb{R}$  of the input image.

Such energies which assign a real value to a function are called a functionals. How does one minimize functionals where the argument is a function  $u(x)$  (rather than a finite number of parameters)?

### **Functional Minimization & Euler-Lagrange Equation**

• As a necessary condition for minimizers of a functional the associated Euler-Lagrange equation must hold. For a functional of the form

$$
E(u)=\int \mathcal{L}(u,u')\,dx,
$$

it is given by

$$
\frac{dE}{du} = \frac{\partial \mathcal{L}}{\partial u} - \frac{d}{dx} \frac{\partial \mathcal{L}}{\partial u'} = 0
$$

- The central idea of variational methods is therefore to determine solutions of the Euler-Lagrange equation of a given functional. For general non-convex functionals this is a difficult problem.
- <span id="page-6-0"></span>• Another solution is to start with an (appropriate) function  $u_0(x)$  and to modify it step by step such that in each iteration the value of the functional is decreased. Such methods are called descent methods.

#### **Gradient Descent**

One specific descent method is called gradient descent or steepest descent. The key idea is to start from an initialization  $u(x, t = 0)$  and iteratively march in direction of the negative energy gradient.

For the class of functionals considered above, the gradient descent is given by the following partial differential equation:

$$
\begin{cases}\n u(x,0) = u_0(x) \\
\frac{\partial u(x,t)}{\partial t} = -\frac{dE}{du} = -\frac{\partial \mathcal{L}}{\partial u} + \frac{d}{dx}\frac{\partial \mathcal{L}}{\partial u'}.\n\end{cases}
$$

[Euler-Lagrange](#page-6-0) **Equation** 

[Gradient Descent](#page-7-0)

[Adaptive Smoothing](#page-9-0)

[Euler and Lagrange](#page-11-0)

Specifically for  $\mathcal{L}(u, u') = \frac{1}{2} (u(x) - f(x))^2 + \frac{\lambda}{2} |u'(x)|^2$  this means:

$$
\frac{\partial u}{\partial t} = (f - u) + \lambda u''.
$$

<span id="page-7-0"></span>If the gradient descent evolution converges:  $\partial u / \partial t = -\frac{dE}{du} = 0$ , then we have found a solution for the Euler-Lagrange equation.

### **Image Smoothing by Gradient Descent**

 $E(u) = \int (f - u)^2 dx + \lambda \int |\nabla u|^2 dx \rightarrow \text{min}.$ 

 $E(u) = \int |\nabla u|^2 dx \rightarrow \text{min}.$

### **Leonhard Euler**

Leonhard Euler (1707 – 1783)

- Published 886 papers and books, most of these in the last 20 years of his life. He is generally considered the most influential mathematician of the 18th century.
- Contributions: Euler number, Euler angle, Euler formula, Euler theorem, Euler equations (for liquids), Euler-Lagrange equations,...
- <span id="page-11-0"></span>• 13 children

### **Joseph-Louis Lagrange**

Joseph-Louis Lagrange (1736 – 1813)

- born Giuseppe Lodovico Lagrangia (in Turin). Autodidact.
- At the age of 19: Chair for mathematics in Turin.
- Later worked in Berlin (1766-1787) and Paris (1787-1813).
- 1788: *La Méchanique Analytique*.
- <span id="page-12-0"></span>• 1800: *Leçons sur le calcul des fonctions*.
