Third Derivatives

Gauss curvature $K(p) = \det(\nu(u))$ depends on the derivatives of N.

To this end let

$$\partial_{\ell j i} x = \sum_{k=1}^{2} \partial_{\ell} \Gamma_{ij}^{k} \partial_{k} x + \Gamma_{ij}^{k} \partial_{\ell k} x - \partial_{\ell} \alpha_{ij} N - \alpha_{ij} \partial_{\ell} N.$$

Observing that $\partial_{211}x = \partial_{121}x$, we obtain for the ∂_2x -component:

$$\partial_2 \Gamma_{11}^2 + \sum_{k=1}^2 \Gamma_{11}^k \Gamma_{2k}^2 - \alpha_{11} \nu_2^2 = \partial_1 \Gamma_{12}^2 + \sum_{k=1}^2 \Gamma_{12}^k \Gamma_{1k}^2 - \alpha_{12} \nu_1^2$$

In other words, $\alpha_{11}\nu_2^2-\alpha_{12}\nu_1^2$ is an intrinsic expression.

IN2238 - Analysis of Three-Dimensional Shapes

13. Gauss Curvature – 5 / 24

Theorema Egregium

The following expression is intrinsic:

$$\begin{aligned} \alpha_{11}\nu_2^2 - \alpha_{12}\nu_1^2 = &\alpha_{11}\sum_{k=1}^2 g^{2k}\alpha_{k2} - \alpha_{12}\sum_{k=1}^2 g^{2k}\alpha_{k1} \\ = &g^{22}\left[\alpha_{11}\alpha_{22} - \alpha_{12}\alpha_{21}\right] + g^{21}\left[\alpha_{11}\alpha_{12} - \alpha_{12}\alpha_{11}\right] \\ = &g_{11}\frac{\alpha_{11}\alpha_{22} - \alpha_{12}\alpha_{21}}{g_{11} \cdot g_{22} - g_{12}^2} = g_{11}K \end{aligned}$$

Theorem 1 (Theorema Egregium). The Gauss curvature K is an intrinsic feature. In particular, we have

$$K = \frac{1}{g_{11}} \left[\left(\partial_2 \Gamma_{11}^2 - \partial_1 \Gamma_{12}^2 \right) + \sum_{k=1}^2 \left(\Gamma_{11}^k \Gamma_{2k}^2 - \Gamma_{12}^k \Gamma_{1k}^2 \right) \right]$$

IN2238 - Analysis of Three-Dimensional Shapes

Riemann Curvature Tensor

For the Theorema Egregium, we separated the term $\partial_{211}x - \partial_{121}x$ in an intrinsic part (using Christoffel Symbols) and an extrinsic part.

Since $\partial_{211}x = \partial_{121}x$, we were able to express the "extrinsic part" with the help of the Christoffel symbols.

Riemann used this insight in order to define the **Riemann Curvature Tensor** R. Given two vector fields X and Y it assigns to each vector field Z and new vector field R(X,Y)Z. If X and Y are given as $\partial_i x$ and $\partial_i x$ of a coordinate map x, R is defined via

$$R(X,Y)Z = \nabla_X \nabla_Y Z - \nabla_Y \nabla_X Z$$

In other words, the Gauss curvature can be intrinsically written as

$$K = \frac{\langle R(\partial_2 x, \partial_1 x) \partial_1 x, \partial_2 x \rangle}{\det(g)}$$

Gauss-Bonnet

Moving Frame

Given a coordinate map $x: U \to M$, the vector fields $\partial_1 x$ and $\partial_2 x$ form a base. Using Gram-Schmidt, we can create three orthonormal vector fields $Y_1, Y_2, Y_3: M \to \mathbb{R}^3$ via (p = x(u))

$$Y_1(p) = \frac{\partial_1 x(u)}{\|\partial_1 x(u)\|}$$

$$Y_2(p) = \frac{\partial_2 x(u) - \langle Y_1(p), \partial_2 x(u) \rangle}{\|\partial_2 x(u) - \langle Y_1(p), \partial_2 x(u) \rangle\|}$$

$$Y_3(p) = Y_1(p) \times Y_2(p)$$

We call these three vector fields a **moving frame**.

Note that a moving frame can not necessarily be derived from a coordinate map x, but it is quite usefull to have an orthonormal system at each point of the coordinate domain U respectively its codomain x(U).

Derivatives of the Moving Frame

The differentials $DY_i(p) \colon T_pM \to \mathbb{R}^3$ can be written as

$$DY_i(p)[v] = \sum_{j=1}^3 \langle \omega_{ij}(p), v \rangle Y_j(p) \qquad \qquad \omega_{ij}(p) \in T_p M$$

Since we have $\langle Y_i,Y_j
angle=0$, we obtain

$$0 = D \langle Y_i(p), Y_j(p) \rangle [v] = \langle DY_i(p)[v], Y_j(p) \rangle + \langle Y_i(p), DY_j(p)[v] \rangle$$

= $\langle \omega_{ij}(p) + \omega_{ji}(p), v \rangle$.

This means, we have

$$\begin{pmatrix} DY_1(p)[v] \\ DY_2(p)[v] \\ \Box Y_3(p)[v] \end{pmatrix} = \begin{pmatrix} 0 & \langle \omega_{12}(p), v \rangle & \langle \omega_{13}(p), v \rangle \\ -\langle \omega_{12}(p), v \rangle & 0 & \langle \omega_{23}(p), v \rangle \\ -\langle \omega_{13}(p), v \rangle & -\langle \omega_{23}(p), v \rangle & 0 \end{pmatrix} \cdot \begin{pmatrix} Y_1(p) \\ Y_2(p) \\ Y_3(p) \end{pmatrix}$$

Winding Number for Circles

Given a closed non-intersecting curve $\gamma: I \to U$ and its corresponding curve $c = x \circ \gamma: I \to M$, we can define the angle function $\theta: c(I) \to \mathbb{R}$ via (p = x(u) = c(t))

$$\theta(p) = \measuredangle(\dot{c}(t), Y_1(p))$$

 $\theta(p)$ is unique up to multiples of 2π , but if we fix $\theta(c(0)) \in [0, 2\pi)$ there is only one unique $\theta(\cdot)$ that remains continuous.

For this setup, we have

$$\int_{c(I)} \theta'(p) \,\mathrm{d}p = \theta(c(1)) - \theta(c(0)) = 2\pi$$

Recap: Geodesic Curvature

Given a curve $c: (0, L) \to M$ that is parametrized by arc-length, we know that $\langle \dot{c}(t), \ddot{c}(t) \rangle = 0$. Since $\frac{\nabla}{\mathrm{dt}} \dot{c}(p)$ contains the component of $\ddot{c}(t)$ in $T_p M$, we have

$$\frac{\nabla}{\mathrm{dt}}\dot{c}(p) = \kappa_g(p)\dot{c}(t)^{\perp},$$

where $\dot{c}(t)^{\perp}$ is the vector in T_pM that is normal to $\dot{c}(t).$

Using the angle function θ , we obtain

$$\kappa_g(p) = \left\langle \frac{\nabla}{\mathrm{dt}} \dot{c}(p), \dot{c}(t)^{\perp} \right\rangle$$

with

$$\begin{pmatrix} \dot{c}(t) \\ \dot{c}(t)^{\perp} \end{pmatrix} = \begin{pmatrix} \cos(\theta(p)) & \sin(\theta(p)) \\ -\sin(\theta(p)) & \cos(\theta(p)) \end{pmatrix} \cdot \begin{pmatrix} Y_1(p) \\ Y_2(p) \end{pmatrix}$$

IN2238 - Analysis of Three-Dimensional Shapes

13. Gauss Curvature – 16 / 24

Integrating Geodesic Curvature

We have

$$\nabla_{\dot{c}}\dot{c} = \cos(\theta)\nabla_{\dot{c}}Y_1 + \sin(\theta)\nabla_{\dot{c}}Y_2 - \sin(\theta)\theta'Y_1 + \cos(\theta)\theta'Y_2$$

and therefore

$$\kappa_g = \langle \nabla_{\dot{c}} \dot{c}, -\sin(\theta) Y_1 + \cos(\theta) Y_2 \rangle$$

=\theta' + \langle \cos(\theta) \nabla_{\circ} Y_1 + \sin(\theta) \nabla_{\circ} Y_2, -\sin(\theta) Y_1 + \cos(\theta) Y_2 \rangle
=\theta' + \langle \omega_{12}, \circ \rangle

In other words

$$-\sum_{i<3}\int_{\mathrm{Im}\,c_i} \langle \omega_{12}(p), \dot{c}_i(t)\rangle \,\mathrm{dp} + \sum_{i<3}\int_{\mathrm{Im}\,c_i} \kappa_g(p) \,\mathrm{dp} + \sum_{i<3} \alpha_i = 2\pi$$

IN2238 - Analysis of Three-Dimensional Shapes

13. Gauss Curvature – 17 / 24

Integration Theorem of Green

Given a vector field $V \colon \mathbb{R}^2 \to \mathbb{R}^2$, and $S = [0,1] \times [0,1]$ the unit square. Then we have

$$\int_{S} \partial_1 V^2(x, y) - \partial_2 V^1(x, y) \, \mathrm{dx} \, \mathrm{dy} = \int_0^1 V^2(1, y) - V^2(0, y) \, \mathrm{dy} + \int_0^1 V^1(x, 0) - V^1(x, 1) \, \mathrm{dx}$$

In other words, we have $\int_S \partial_1 V^2(p) - \partial_2 V^1(p) dp = \int_{\partial S} V^1 dx + V^2 dy.$

This is the **Green's theorem**, which is also true for general open sets S with a smooth boundary ∂S parametrized by $c: [0;1] \rightarrow \partial S$:

$$\int_{S} \partial_1 V^2(p) - \partial_2 V^1(p) \,\mathrm{dp} = \int_{\partial S} V^1 \,\mathrm{dx} + V^2 \,\mathrm{dy} = \int_0^1 \langle V(c(t)), \dot{c}(t) \rangle \,\mathrm{dt}$$

IN2238 - Analysis of Three-Dimensional Shapes

13. Gauss Curvature - 18 / 24

Integrating ω_{12}

In order to express the integral of $\langle \omega_{12},\dot{c}\rangle$ in means of p alone, we have

$$\int_{\operatorname{Im} c_i} \langle \omega_{12}(p), \dot{c}(t) \rangle \, \mathrm{dp} = \int_{\operatorname{Im} c_i} \langle \nabla_{\dot{c}} Y_1(p), Y_2(p) \rangle \, \mathrm{dp}$$

Analogously to the Green integration theorem, one can show that

$$\int_{\partial T} \left\langle \nabla_{\dot{c}} Y_1(p), Y_2(p) \right\rangle \mathrm{dp} = \int_T \left\langle R(Y_1, Y_2) Y_1(p), Y_2(p) \right\rangle \mathrm{dp} = -\int_T K(p) \, \mathrm{dp}$$

In other words the Theorem of Gauss-Bonnet for Triangles is

$$\int_{T} K(p) \,\mathrm{dp} + \int_{\partial T} \kappa_g(p) \,\mathrm{dp} + \sum_{i < 3} \alpha_i = 2\pi$$

IN2238 - Analysis of Three-Dimensional Shapes

13. Gauss Curvature – 19 / 24

Gauss-Bonnet without Boundary

Let us assume we have a smooth triangulation of a closed surface M that uses the vertex set V, the edge set E and the face set F, then we have

$$2\pi \cdot |F| = \sum_{T \in F} \left[\int_T K(p) \, \mathrm{dp} + \int_{\partial T} \kappa_g(p) \, \mathrm{dp} + \sum_{i < 3} \alpha_i^{(T)} \right]$$
$$= \int_M K(p) \, \mathrm{dp} + |E| \cdot 2\pi - |V| \cdot 2\pi$$

In other words the Theorem of Gauss-Bonnet for Closed Surfaces is

$$\int_{M} K(p) \, \mathrm{dp} = 2\pi \left(|F| - |E| + |V| \right)$$

IN2238 - Analysis of Three-Dimensional Shapes

13. Gauss Curvature – 20 / 24

Gauss-Bonnet with Smooth Boundary

Let us assume we have a surface M with a smooth boundary. Further assume a smooth triangulation that uses the vertex set V, the edge set E and the face set F. Then we have

$$2\pi \cdot |F| = \sum_{T \in F} \left[\int_T K(p) \, \mathrm{dp} + \int_{\partial T} \kappa_g(p) \, \mathrm{dp} + \sum_{i < 3} \alpha_i^{(T)} \right]$$
$$= \int_M K(p) \, \mathrm{dp} + \int_{\partial M} \kappa_g(p) \, \mathrm{dp} + |E| \cdot 2\pi - |V| \cdot 2\pi$$

In other words the Theorem of Gauss-Bonnet for Surfaces With Smooth Boundaries is

$$\int_{M} K(p) \,\mathrm{dp} + \int_{\partial M} \kappa_g(p) \,\mathrm{dp} = 2\pi \left(|F| - |E| + |V| \right)$$

IN2238 - Analysis of Three-Dimensional Shapes

13. Gauss Curvature – 21 / 24

Euler Chracteristic

Given a triangulation (V, E, F) of a surface M, we call

 $\chi(M) = |V| - |E| + |F| \in \mathbb{Z}$

the **Euler Characteristic** of M.

Due to the Gauss-Bonnet theorem, we know that

$$\chi(M) = \frac{\int_M K(p) \,\mathrm{d}p + \int_{\partial M} \kappa_g(p) \,\mathrm{d}p}{2\pi}$$

is a global property of M.

For every triangulation (V,E,F) of \mathbb{S}^2 we have

$$|V| - |E| + |F| = \chi(\mathbb{S}^2) = 2$$

IN2238 - Analysis of Three-Dimensional Shapes

13. Gauss Curvature – 23 / 24

Gauss Curvature at a Vertex

Given a discrete triangulation (V, E, F) of a surface M, we assume that at a vertex $v \in V$, we have k triangles T_1, \ldots, T_k with the angles α_i , β_i and γ_i (γ_i at v). It is common to use the following approximation of the Gauss curvature as a feature (point descriptor)

$$K(v) := \frac{\int_{\bigcup_{i=1}^{k} \frac{1}{3}T_i} K(p) \, \mathrm{d}p}{\sum_{i=1}^{k} \frac{1}{3} \operatorname{area}(T_i)} \approx \frac{2\pi - \sum_{i=1}^{k} \gamma_i}{\sum_{i=1}^{k} \frac{1}{3} \operatorname{area}(T_i)}$$

IN2238 - Analysis of Three-Dimensional Shapes

13. Gauss Curvature – 24 / 24
