# 2. Pseudo-Boolean Optimization

2 / 33

#### **Pseudo-Boolean Function**

3 / 33

#### **Boolean Variables**

A Boolean variable  $x \in \mathbb{B}$  can either be *true* or *false*.

To simplify the notation, we denote the Boolean set as  $\mathbb{B}:=\{0,1\}$ . Here, 0 and 1 are identified with *false* and *true* respectively.

 $\mathbb{B}$  forms a **totally ordered set**, *i.e.*,

$$x \leqslant y \text{ and } y \leqslant x \Leftrightarrow x = y$$
 (for all  $x, y \in \mathbb{B}$ )  
 $x \leqslant y \text{ and } y \leqslant z \Rightarrow x \leqslant z$  (for all  $x, y, z \in \mathbb{B}$ )  
 $x \leqslant y \text{ or } y \leqslant x$  (for all  $x, y \in \mathbb{B}$ )

For two Boolean variables  $x, y \in \mathbb{B}$ , we denote

$$x \wedge y := \min\{x, y\} \qquad \qquad x \vee y := \max\{x, y\}$$

IN2245 - Combinatorial Optimization in Computer Vision

2. Pseudo-Boolean Optimization – 4 / 33

#### **Powerset**

Given an arbitrary set  $\Omega$ , we denote the *powerset* of  $\Omega$  as  $\mathcal{P}(\Omega)$  or  $2^{\Omega}$ .

The powerset is the unique set that contains all subsets of  $\Omega$ .

For two sets  $A, B \in \mathcal{P}(\Omega)$ , the subset relationship

$$A \subset B :\Leftrightarrow [\forall i \in A : i \in B]$$

makes  $\mathcal{P}(\Omega)$  a partially ordered set, i.e.,

$$A \subset B \text{ and } B \subset A \Leftrightarrow A = B$$
 (for all  $A, B \in \mathcal{P}(\Omega)$ )  
 
$$A \subset B \text{ and } B \subset C \Rightarrow A \subset C$$
 (for all  $A, B, C \in \mathcal{P}(\Omega)$ )

For two subsets  $A, B \in \mathcal{P}(\Omega)$ , we denote

$$A \cap B := \inf\{A, B\}$$

$$A \cup B := \sup\{A, B\}$$

IN2245 - Combinatorial Optimization in Computer Vision

2. Pseudo-Boolean Optimization – 5 / 33

#### Union and Intersection

Note that for  $A, B \in \mathcal{P}(\Omega)$ ,  $\inf\{A, B\}$  is defined as the maximal lower bound of A and B, i.e.,  $\inf\{A, B\}$  is the  $C \in \mathcal{P}(\Omega)$  such that

- lacksquare C is a lower bound, i.e.,  $C \subset A$  and  $C \subset B$ .
- For all other lower bounds D,  $D \subset C$  holds.

One can show that  $\cap$  and  $\cup$  coincides with the classial notion of *union* and *intersection*:

$$A \cup B = \{i \in \Omega | i \in A \text{ or } i \in B\}$$
$$A \cap B = \{i \in \Omega | i \in A \text{ and } i \in B\}$$

IN2245 - Combinatorial Optimization in Computer Vision

2. Pseudo-Boolean Optimization - 6 / 33

#### **Subsets as Boolean Mappings**

To each subset  $A \in \mathcal{P}(\Omega)$ , we can define the characteristic function

$$\chi_A: \Omega \to \mathbb{B}$$
$$i \mapsto [i \in A]$$

For two characteristic functions  $\chi_A$  and  $\chi_B$ , we can define

$$[\chi_A \wedge \chi_B](i) := \chi_A(i) \wedge \chi_B(i) \qquad [\chi_A \vee \chi_B](i) := \chi_A(i) \vee \chi_B(i)$$

and we obtain

$$\chi_A \wedge \chi_B = \chi_{A \cap B} \qquad \qquad \chi_A \vee \chi_B = \chi_{A \cup B}$$

The partial ordering of  $\mathcal{P}(\Omega)$  is induced by the total ordering of  $\mathbb{B}$ .

If we replace  $\mathbb{B}$  with a totally ordered set  $\mathcal{L}$ , wie can replace  $\mathcal{P}(\Omega)$  with  $\mathcal{L}^{\Omega}$ .

IN2245 - Combinatorial Optimization in Computer Vision

2. Pseudo-Boolean Optimization – 7 / 33

#### **Boolean Function**

A Boolean function  $E: 2^{\Omega} \to \mathbb{B}$  assigns to every subset  $A \subset \Omega$  a Boolean value E(A).

One can use a Boolean function in order to test certain properties:

$$E_1(A) = [A \neq \varnothing]$$

 $E_2(A) = [A \text{ is connected}]$ 

 $E_3(A) = [A \text{ is a square}]$ 

 $E_4(A) = [A \text{ is almost circular}]$ 

In Computer Vision, we are usually interested in problems that are beyond a pure satisfiability test.

We are not interested whether A is almost circular. Instead, we would like to evaluate some sort of dissimilarity measure between A and a perfect disc.

IN2245 - Combinatorial Optimization in Computer Vision

2. Pseudo-Boolean Optimization - 8 / 33

#### **Pseudo-Boolean Function**

A pseudo-Boolean function  $E: 2^{\Omega} \to \mathbb{R}$  assigns to every subset  $A \subset \Omega$  a real value E(A).

In the following, we will identify a subset  $A \subset \Omega$  with its characteristic function  $\chi_A : \Omega \to \mathbb{B}$ . Therefore, we may also refer to E as a functional.

In the literature, one usually talks about E as a function if  $\Omega$  is a finite set. E is referred to as a functional if  $\Omega$  is a continuous set (real-valued vector spaces, finite-dimensional manifolds, etc.).

In this lecture, we will only consider finite sets  $\Omega$ .

See Variational Methods for Computer Vision for functional-driven optimization methods.

IN2245 - Combinatorial Optimization in Computer Vision

2. Pseudo-Boolean Optimization – 9 / 33

#### **Pseudo-Boolean Optimization**

Most Computer Vision problems can be cast as the minimization of a pseudo-Boolean function  $E: 2^{\Omega} \to \mathbb{R}$ .

Given  $E: 2^{\Omega} \to \mathbb{R}$ , we are interested in the global minimum  $\min_{A \subset \Omega} E(A)$  and in one of its global minimizers  $A \in \operatorname{argmin} E$ ,

$$\operatorname{argmin} E := \{ A \subset \Omega | E(A) \leqslant E(B) \text{ for all } B \subset \Omega \}.$$

Since  $\Omega$  is finite, we know that  $\operatorname{argmin} E$  is not empty, but in general it may contain more than one global minimizer.

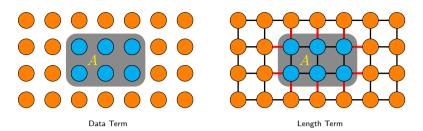

If the computation of a global minimizer is NP-hard, we are also satisfied with an approximation. A set  $S \subset \Omega$  is called an  $(1 + \epsilon)$ -approximation of  $\operatorname{argmin} E$ , if the following holds

$$E(S) \le (1 + \epsilon) \cdot \min_{A \subset \Omega} E(A).$$

IN2245 - Combinatorial Optimization in Computer Vision

2. Pseudo-Boolean Optimization – 10 / 33

# **Binary Image Segmentation**

Segmenting an image can be cast as minimizing the energy

$$E_{\mathsf{Data}}(A) = \sum_{i \in A} f(i)$$

It is common to combine it with a length term

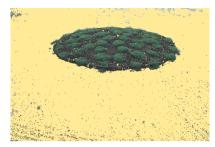

$$E_{\mathsf{Length}}(A) = \sum_{i \in A} \sum_{\substack{j \notin A, \\ |i-j|=1}} 1$$

IN2245 - Combinatorial Optimization in Computer Vision

2. Pseudo-Boolean Optimization – 11 / 33

#### **Binary Image Segmentation**

Given Image

Minimizing Data Term

Minimizing Data + Length Term

$$\underset{A \subset \Omega}{\operatorname{argmin}} E(A) = \underset{i \in \Omega}{\operatorname{argmin}} \sum_{i \in \Omega \setminus A} f_0(i) + \sum_{i \in A} f_1(i) + \operatorname{length}(A)$$

$$= \underset{A \subset \Omega}{\operatorname{argmin}} \sum_{i \in \Omega} f_0(i) + \sum_{i \in A} [\underbrace{f_1(i) - f_0(i)}_{=:f(i)}] + \operatorname{length}(A)$$

$$= \underset{A \subset \Omega}{\operatorname{argmin}} \sum_{i \in A} f(i) + \operatorname{length}(A)$$

We will show that this energy can be minimized in polynomial time.

IN2245 - Combinatorial Optimization in Computer Vision

2. Pseudo-Boolean Optimization – 12 / 33

Submodularity 13 / 33

#### **Modular Functions**

The minimization of a pseudo-Boolean function  $E \colon 2^{\Omega} \to \mathbb{R}$  (with  $E(\emptyset) = 0$ ) becomes very easy, if E is modular, i.e.,

$$E(A \cup B) + E(A \cap B) = E(A) + E(B)$$
 (for all  $A, B \in 2^{\Omega}$ )

For disjoint  $A, B \in 2^{\Omega}$ , we have  $E(A \sqcup B) = E(A) + E(B)$ , which implies

$$E(A) = \sum_{i \in A} E(\{i\}).$$

A global minimizer of the modular function  ${\cal E}$  is therefore

$$A = \{i \in \Omega | E(\{i\}) < 0\}$$

and it can be found in  $\mathcal{O}(N)$  time, where  $N:=|\Omega|$  is the cardinality of  $\Omega$ .

IN2245 - Combinatorial Optimization in Computer Vision

2. Pseudo-Boolean Optimization – 14 / 33

#### Submodularity and Supermodularity

A pseudo-Boolean function  $E \colon 2^\Omega \to \mathbb{R}$  is called submodular if

$$E(A \cup B) + E(A \cap B) \leqslant E(A) + E(B) \tag{for all } A, B \in 2^{\Omega})$$

A pseudo-Boolean function  $E \colon 2^{\Omega} \to \mathbb{R}$  is called supermodular if

$$E(A \cup B) + E(A \cap B) \geqslant E(A) + E(B)$$
 (for all  $A, B \in 2^{\Omega}$ )

Modular functions are submodular and supermodular. Modular, sub- and supermodular functions are closed w.r.t. summation and positive scaling.

Minimizing an arbitrary submodular functions can be done in polynomial time [Grötschel, Lovász, Schrijver, 1981].

The minimization of supermodular functions is in general NP-hard.

IN2245 - Combinatorial Optimization in Computer Vision

2. Pseudo-Boolean Optimization – 15 / 33

#### Submodularity w.r.t. 2 Variables

Let  $E \colon 2^{\Omega} \to \mathbb{R}$  be submodular and let  $S \in 2^{\Omega}$  and  $i, j \in \Omega \backslash S$ . Then

$$E(S \cup \{i, j\}) + E(S) \le E(S \cup \{i\}) + E(S \cup \{j\}). \tag{1}$$

If we define  $E_2 : \mathbb{B} \times \mathbb{B} \to \mathbb{R}$  via  $E_2(b_1, b_2) := E(S + b_1 \cdot \{i\} + b_2 \cdot \{j\})$ , we can rewrite (1) as

$$E_2(1,1) + E_2(0,0) \le E_2(0,1) + E_2(1,0)$$
 (2)

If for a pseudo-Boolean function  $E: 2^{\Omega} \to \mathbb{R}$ , the Equation (1) is satisfied for all S, i, j, the energy E is in fact submodular. Some authors use therefore (2) as definition for submodularity.

IN2245 - Combinatorial Optimization in Computer Vision

2. Pseudo-Boolean Optimization - 16 / 33

## **Submodular Functions**

 $E_{\mathsf{Length}} \colon 2^\Omega \to \mathbb{R}$  is submodular and  $E_{\mathsf{Data}} \colon 2^\Omega \to \mathbb{R}$  is modular.

Iff  $E\colon 2^\Omega\to\mathbb{R}$  is a supermodular function, then  $-E\colon 2^\Omega\to\mathbb{R}$  is submodular.

If  $E\colon 2^\Omega\to\mathbb{R}$  is submodular,  $T\subset\Omega$ , then  $E|T\colon 2^\Omega\to\mathbb{R}$  is submodular with

$$E|T(A) := E(T \cap A).$$

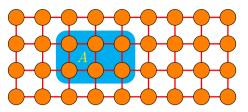

If  $H \colon \mathbb{R} \to \mathbb{R}$  is a concave function, then  $E_H \colon 2^\Omega \to \mathbb{R}$  is submodular with

$$E_H(A) := H(|A|).$$

IN2245 - Combinatorial Optimization in Computer Vision

2. Pseudo-Boolean Optimization – 17 / 33

# Weighted Contour Length

Weighted Contour Length (w < 0)

The weighted contour length with negative weights is a supermodular energy.

Minimizing the length is equivalent to maximizing the cut with positive weights.

The Maximum Cut problem is NP hard.

Thus, minimizing a supermodular function is in general NP hard.

IN2245 - Combinatorial Optimization in Computer Vision

2. Pseudo-Boolean Optimization – 18 / 33

Lovász Extension 19 / 33

#### **Convex Closure**

In order to analyze a pseudo-Boolean function  $E \colon \mathbb{B}^\Omega \to \mathbb{R}$ , one can extend it to a function  $\bar{E} \colon [0,1]^\Omega \to \mathbb{R}$  such that  $\bar{E} | \mathbb{B}^\Omega = E$ .

Using a specific totall ordering < of the  $N \in \mathbb{N}$  elements in  $\Omega$ 

$$i_1 < i_2 < \ldots < i_N$$

we can write  $E:\mathbb{B}^N \to \mathbb{R}$  and  $\bar{E}\colon [0,1]^N \to \mathbb{R}.$ 

The convex closure  $E^-\colon [0,1]^N \to \mathbb{R}$  is defined as

$$E^{-}(x) = \min \left\{ \sum_{S \subset \Omega} \alpha_S \cdot E(S) \middle| x = \sum_{S \subset \Omega} \alpha_S \cdot S, \sum_{S \subset \Omega} \alpha_S = 1, \alpha_S \geqslant 0 \right\}.$$

Note that  $E^-$  is piecewise linear and hence non-differentiable.

IN2245 - Combinatorial Optimization in Computer Vision

2. Pseudo-Boolean Optimization – 20 / 33

#### **Convex Closure**

**Theorem 1.** Convex closure  $E^-$  of a pseudo-Boolean function E is convex.

 $\textit{Proof.} \quad \text{Let } x^0, x^1 \in [0,1]^N \text{, } \lambda \in [0,1] \text{ and } x^\lambda := (1-\lambda) \cdot x^0 + \lambda \cdot x^1. \text{ We have to show that } E^-(x^\lambda) \leqslant (1-\lambda)E^-(x^0) + \lambda E^-(x^1). \text{ We have to show that } E^-(x^\lambda) \leqslant (1-\lambda)E^-(x^0) + \lambda E^-(x^1).$ 

$$E^{-}(x^{0}) = \sum_{S \subset \Omega} \alpha_{S}^{0} \cdot E(S)$$

$$x^{0} = \sum_{S \subset \Omega} \alpha_{S}^{0} \cdot S$$

$$E^{-}(x^{1}) = \sum_{S \subset \Omega} \alpha_{S}^{1} \cdot E(S)$$

$$x^{1} = \sum_{S \subset \Omega} \alpha_{S}^{1} \cdot S$$

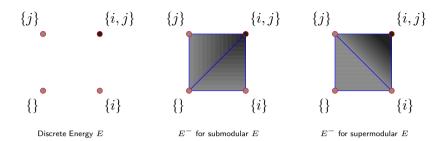

Defining  $\alpha_S^{\lambda}:=(1-\lambda)\cdot\alpha_S^0+\lambda\cdot\alpha_S^1$ , we obtain

$$E^{-}(x^{\lambda}) \leqslant \sum_{S \subset \Omega} \alpha_{S}^{\lambda} \cdot E(S) = (1 - \lambda)E^{-}(x^{0}) + \lambda E^{-}(x^{1})$$

IN2245 - Combinatorial Optimization in Computer Vision

2. Pseudo-Boolean Optimization - 21 / 33

# Convex Closure (N=2)

Assume, we have  $\Omega = \{i,j\}$  and the pseudo-Boolean function  $E:2^\Omega \to \mathbb{R}$ 

$$E(\emptyset) = E(\{i\}) = E(\{j\}) = 0$$

$$E(\{i,j\}) = \alpha \in \mathbb{R}$$

E is submodular for  $\alpha \leq 0$  and supermodular for  $\alpha \geq 0$ .

The convex extension  $E^-$  is different for  $\alpha < 0$  resp.  $\alpha > 0$ .

IN2245 - Combinatorial Optimization in Computer Vision

2. Pseudo-Boolean Optimization – 22 / 33

#### Lovász Extension

In general, it may take exponential time in order to evaluate  ${\cal E}^-.$ 

The Lovász extension on the other hand can be computed in linear time

$$E^{L}(x) = \sum_{n=0}^{k} \alpha_n \cdot E(S_n)$$
 for  $x = \sum_{n=0}^{k} \alpha_n \cdot S_n$  
$$\sum_{n=0}^{k} \alpha_n = 1, \alpha_n \ge 0$$
 
$$\varnothing = S_0 \subset \ldots \subset S_k$$

**Example 1.** Let  $\Omega=\{i,j\}$ ,  $E\colon \mathbb{B}^\Omega\to\mathbb{R}$  a pseudo-Boolean function and f=(0.1,0.6). Then we have

$$S_0 = \emptyset; \quad S_1 = \{j\}; \quad S_2 = \{i, j\}$$
  
$$E^L(x) = 0.4 \cdot E(S_0) + 0.5 \cdot E(S_1) + 0.1 \cdot E(S_2)$$

IN2245 - Combinatorial Optimization in Computer Vision

2. Pseudo-Boolean Optimization – 23 / 33

#### Lovász Extension (Representation)

**Theorem 2.** Let  $x \in [0,1]^N$ . Then there is a  $k \le N$ , a chain  $\emptyset \subset S_0 \subset \ldots \subset S_k \subset \Omega$  and  $\alpha_0,\ldots,\alpha_k>0$  such that  $\sum_{n=0}^k \alpha_n=1$  and  $x=\sum_{n=0}^k \alpha_n S_n$ . This representation is unique.

*Proof.* Induction over |X| with  $X = \{x_i | x_i > 0\}$ . We will prove  $k = |X| \leq N$ .

**Base Case:** Assume that |X| = 0.

 $X=\emptyset$  implies x=0. We have uniquely k=0,  $S_0=\emptyset$  and  $\alpha_0=1$ .

**Inductive Step:** Assume the theorem is true for all x' with |X'| < |X|.

The biggest set  $S_k$  has to be  $\{i|x_i>0\}$  and we have to choose  $\alpha_k=\min X$ . Otherwise, x is not representable as a convex combination. Let now  $x' := x - \alpha_k S_k$ . For the set X', we have |X'| = |X| - 1.

Therefore, there exists a unique representation  $x' = \sum_{n=0}^{k-1} \alpha_n' S_i'$ . Since  $\max X' \leqslant 1 - \alpha_k$ , we have  $S_0' = \varnothing$  and  $\alpha_0' \geqslant \alpha_k$ . Setting  $\alpha_0 = \alpha_0' - \alpha_k$ ,  $\alpha_n = \alpha_n'$  for 0 < i < k and  $S_n = S_n'$  for  $0 \leqslant n < k$  provides us with a representation for x.

IN2245 - Combinatorial Optimization in Computer Vision

2. Pseudo-Boolean Optimization - 24 / 33

#### Lovász Extension

**Theorem 3.** A pseudo-Boolean function E is submodular iff  $E^- = E^L$ .

Proof.

Case 1: E is not submodular.

Then, there exist  $S \subset \Omega$  and  $i, j \in \Omega \backslash S$  such that

$$E(S + \{i, j\}) + E(S) > E(S + \{i\}) + E(S + \{j\})$$

If we choose  $x=S+\frac{1}{2}\{i\}+\frac{1}{2}\{j\}$ , we have

$$E^{L}(x) = \frac{1}{2} (E(S + \{i, j\}) + E(S))$$
  
$$E^{-}(x) \leq \frac{1}{2} (E(S + \{i\}) + E(S + \{j\}))$$

and therefore  $E^L \neq E^-$ .

IN2245 - Combinatorial Optimization in Computer Vision

2. Pseudo-Boolean Optimization – 25 / 33

#### Lovász Extension

Proof (cont.).

Case 2: E is submodular.

Let  $x \in [0,1]^N$  with  $|\Omega| = N$  and

$$\mathcal{A} = \left\{ (\alpha_S)_{S \subset \Omega} \middle| x = \sum_{S \subset \Omega} \alpha_S \cdot S, \sum_{S \subset \Omega} \alpha_S = 1, E^-(x) = \sum_{S \subset \Omega} \alpha_S E(S) \right\}.$$

We choose an  $\alpha \in \mathcal{A}$  that maximizes  $\sum_{S \subset \Omega} \alpha_S \cdot |S|^2$ . We have to prove that the  $\alpha_S$  are only positive for sets that are subsets from one another. Assume that there are  $S, T \subset \Omega$  with  $\alpha_S \geqslant \alpha_T > 0$  and  $|S \setminus T|, |T \setminus S| > 0$ . Replacing  $\alpha_T(S+T)$  with  $\alpha_T(S \cap T + S \cup T)$  does not increase the energy due to submodularity, but

$$|S \cap T|^2 + |S \cup T|^2 = |S|^2 + |T|^2 + 2|S \setminus T| \cdot |T \setminus S| > |S|^2 + |T|^2$$

which contradicts the choice of  $\alpha$ .

IN2245 - Combinatorial Optimization in Computer Vision

2. Pseudo-Boolean Optimization - 26 / 33

#### Lovász Extension

For submodular functions E, we saw

- 1. The Lovász extension  $E^L$  can be evaluated in polynomial time.
- 2. Since  $E^L = E^-$ , we can minimize  $E^L$  in polynomial time.
- 3. Since  $E^L$  is piecewise linear, the minimum is been taken at its boundary. Therefore, the minimum of  $E^L$  is been taken by a set  $S \subset \Omega$ .

[Grötschel, Lovász, Schrijver: The ellipsoid method and its consequences in combinatorial optimization, Combinatorica 1 (1981)]

"The algorithm [...] is based on the ellipsoid method, and uses therefore a heavy framework of division, rounding, and approximation; moreover, it is not practical."

A. Schrijver, 2000

Schrijver's new method takes  $\mathcal{O}(N^5)$  iterations. In each iteration, an  $N \times N$  matrix has to be inverted.

Multilinear Extension 28 / 33

#### **Multilinear Extension**

Another extension of a pseudo-Boolean function  $E: \mathbb{B}^N \to \mathbb{R}$  is the multilinear extension  $\bar{E}: [0,1]^N \to \mathbb{R}$ . It makes use of the fact that for a given set  $A \subset \Omega$  the function

$$F: [0,1]^N \to \mathbb{R}$$
$$(x_1, \dots, x_n) \mapsto \prod_{i \in A} x_i \prod_{i \notin A} (1 - x_i)$$

satisfies

$$F(S) = \begin{cases} 1 & \text{if } S = A \\ 0 & \text{otherwise} \end{cases}$$

The multilinear extension  $\bar{E}$  is defined via

$$\bar{E}(x_1,\ldots,x_n) := \sum_{A \subset \Omega} E(A) \cdot \prod_{i \in A} x_i \prod_{i \notin A} (1 - x_i)$$

IN2245 - Combinatorial Optimization in Computer Vision

2. Pseudo-Boolean Optimization - 29 / 33

## Multilinear Extension (Example)

Consider the pseudo-Boolean function  $E:\mathbb{B}^3\to\mathbb{R}$ 

$x_1$	$x_2$	$x_3$	$E(x_1, x_2, x_3)$
0	0	0	0
0	0	1	0
0	1	0	0
0	1	1	0
1	0	0	1
1	0	1	1
1	1	0	1
1	1	1	0

and its extension  $\bar{E} \colon [0,1]^N \to \mathbb{R}$ :

$$\bar{E}(x_1, x_2, x_3) = x_1(1 - x_2)(1 - x_3) + x_1(1 - x_2)x_3 + x_1x_2(1 - x_3).$$

Using the notation  $\bar{x}:=(1-x)$ , we can write  $\bar{E}$  as

$$\overline{E}(x_1, x_2, x_3) = x_1 \overline{x_2} \overline{x_3} + x_1 \overline{x_2} x_3 + x_1 x_2 \overline{x_3} 
= x_1 (1 - x_2 x_3)$$

IN2245 - Combinatorial Optimization in Computer Vision

2. Pseudo-Boolean Optimization – 30 / 33

#### **Second Derivatives**

**Theorem 4.** Iff E is submodular, we have  $\frac{\partial^2 \bar{E}}{\partial x_i \partial x_j} \leq 0$  for all  $x_i, x_j$ .

Proof. We have

$$\frac{\partial \bar{E}}{\partial x_{i}} = \sum_{A \subset \Omega} E(A) \frac{\partial}{\partial x_{i}} \left[ \prod_{j \in A} x_{j} \prod_{j \notin A} \bar{x}_{j} \right]$$

$$= \sum_{i \in A \subset \Omega} E(A) \left[ \prod_{j \in A, j \neq i} x_{j} \prod_{j \notin A} \bar{x}_{j} \right] - \sum_{i \notin A \subset \Omega} E(A) \left[ \prod_{j \in A} x_{j} \prod_{j \notin A, j \neq i} \bar{x}_{j} \right]$$

$$= \bar{E}(x_{1}, \dots, x_{i-1}, 1, x_{i+1}, \dots, x_{n}) - \bar{E}(x_{1}, \dots, x_{i-1}, 0, x_{i+1}, \dots, x_{n})$$

$$= \sum_{A \subset (\Omega \setminus \{i\})} \left[ E(A+i) - E(A) \right] \left[ \prod_{j \in A} x_{j} \prod_{j \notin A} \bar{x}_{j} \right]$$

IN2245 - Combinatorial Optimization in Computer Vision

2. Pseudo-Boolean Optimization - 31 / 33

#### **Second Derivatives**

Proof (Cont.). For the second derivatives we get

$$\frac{\partial^2 \bar{E}}{\partial x_j \partial x_i} = \frac{\partial}{\partial x_j} \sum_{A \subset (\Omega \setminus \{i\})} [E(A+i) - E(A)] \left[ \prod_{k \in A} x_k \prod_{k \notin A} \bar{x}_k \right]$$

$$= \sum_{A \subset (\Omega \setminus \{i,j\})} [(E(A+i+j) - E(A+j)) - (E(A+i) - E(A))] \cdot \left[ \prod_{j \in A} x_j \prod_{j \notin A} \bar{x}_j \right]$$

It follows that E is submodular iff  $\frac{\partial^2 \bar{E}}{\partial x_i \partial x_i} \leqslant 0$ .
