2 / 36

Higher-order energy functions

So far, we have considered (undirected) **pairwise** graphical models $\mathcal{G} = (\mathcal{V}, \mathcal{E})$, where the corresponding energy function is defined for a labeling $\mathbf{y} \in \mathcal{Y} = \mathcal{Y}_1 \times \cdots \times \mathcal{Y}_{|\mathcal{V}|}$ as

$$E(\mathbf{y}) = \sum_{i \in \mathcal{V}} E_i(y_i) + \sum_{(i,j) \in \mathcal{E}} E_{ij}(y_i, y_j) .$$

The pairwise model suffers from a number of problems stemming from its inability to express high-order dependencies between pixels.

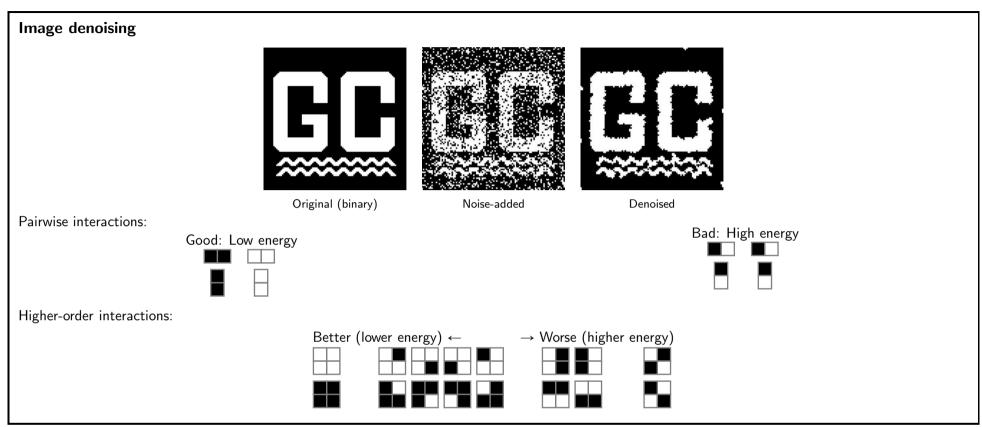

In many computer vision problems, however, one needs to use higher-order relations of the pixels.

$$E(\mathbf{y}) = \sum_{i \in \mathcal{V}} E_i(y_i) + \sum_{(i,j) \in \mathcal{E}} E_{ij}(y_i, y_j) + \sum_{c \in \mathcal{C}} E_c(y_c) ,$$

where $\mathcal C$ is a set of cliques with at least three variables and $y_c \in \times_{i \in c} \mathcal Y_i$.

Multi-camera scene reconstruction

This problem is the generalization of stereo matching (see Lecture 12).

Left view

Middle view

Right view

Reconstruction

We are given three images I_l , I_m and I_r . For each pixel p, on all the three images, we consider a label y_p corresponding to a (discretized) depth value. Note that a pair (p, y_p) specifies a 3D point that has the depth value y_p and is projected to the pixel p.

Let \mathcal{I} be a set of triples of "nearby" 3D points: these points will come from different cameras, but they will share the same depth (i.e. the points are of the form (p, y_p) , (q, y_q) and (r, y_r) , where $y_p = y_q = y_r$ and p, q and p, q

IN2245 - Combinatorial Optimization in Computer Vision

14. Higher-order Clique Reduction – 5 / 36

Multi-camera scene reconstruction

If three pixels have similar intensities, then it is more likely that they see the same scene element than if only two pixels have similar intensities.

The energy function is defined as

$$E(\mathbf{y}) = \sum_{((p,y_p),(q,y_q),(r,y_r)) \in \mathcal{I}} E_{pqr}^l(y_p, y_q, y_r) + \sum_{\alpha \in \{l,m,r\}} \sum_{(i,j) \in \mathcal{N}_{\alpha}} [y_i \neq y_j],$$

where $\mathcal{N}_l, \mathcal{N}_m$ and \mathcal{N}_r are neighborhood systems on pixels corresponding to single camera images,

$$E_{pqr}^{l}(y_p, y_q, y_r) = D(p, q, r) \cdot [y_p = y_q = y_r].$$

The data term enforces photoconsistency, so D(p,q,r) is a function of the intensity difference between p,q and r.

Reduction by substitution

Multi-linear representation

Reminder. any pseudo-Boolean function $f: \mathbb{B}^n \to \mathbb{R}$ can be uniquely written as a *multi-linear function* (see Lecture 2.):

$$f(x_1,\ldots,x_n) = \sum_{S \subset \mathcal{V}} c_S \prod_{i \in S} x_i$$

where $\mathcal{V} = \{1, \dots, n\}$ and $c_S \in \mathbb{R}$.

Remark that for a pseudo-Boolean function f given in the above multi-linear form the following holds:

$$\max_{x_1,\dots,x_n\in\mathbb{B}} f(x_1,\dots,x_n) \leqslant \sum_{S\subset\mathcal{V}} |c_S|.$$

IN2245 - Combinatorial Optimization in Computer Vision

14. Higher-order Clique Reduction – 9 / 36

Reduction by substitution

Rosenberg proposed a method that reduces the minimization of a pseudo–Boolean function of **any degree** to an equivalent problem for **quadratic** pseudo–Boolean function.

Idea: the **product of two variables** xy **is replaced by a new variable** z, which is forced to have the same value as xy at any minimum of the function.

Assume that $x, y, z \in \mathbb{B}$ and define

$$g(x,y,z) = xy - 2xz - 2yz + 3z.$$

Then the following equivalences hold:

$$xy = z \Leftrightarrow g(x, y, z) = 0$$
 and

$$xy \neq z \iff g(x, y, z) > 0$$
.

Note that, of course, the above quadratic expression is not the only one for which such equivalences would hold.

IN2245 - Combinatorial Optimization in Computer Vision

14. Higher-order Clique Reduction – 10 / 36

 $xy = z \Leftrightarrow g(x, y, z) = 0$ and $xy \neq z \Leftrightarrow g(x, y, z) > 0$

Reduction by substitution

\boldsymbol{x}	y	z	xy - 2xz - 2yz + 3z	xy = z
0	0	0	0	yes
0	0	1	3	no
0	1	0	0	yes
0	1	1	1	no
1	0	0	0	yes
1	0	1	1	no
1	1	0	1	no
1	1	1	0	yes

Consider an example pseudo-Boolean function

$$f(x, y, w) = xyw + xy + y.$$

Then replace xy by z and add Mg(x,y,z):

$$\tilde{f}(x, y, w, z) = zw + z + y + Mg(x, y, z)$$
 for $0 < M \in \mathbb{R}$.

Reduction by substitution

$$f(x, y, w) = xyw + xy + y$$

$$\tilde{f}(x, y, w, z) = zw + z + y + Mg(x, y, z) .$$

Let us define M as $M := 1 + \sum_{S \in V} |c_S| = 1 + 3 = 4$.

- If xy = z, then g(x, y, z) = 0, thus $\min \tilde{f}(x, y, w, z) = \min f(x, y, w)$.
- If $xy \neq z$, then $\tilde{f}(x,y,w,z) \geqslant M$. Nevertheless, $\max f(x,y,w) < M$, therefore it is impossible for \tilde{f} to take the minimum whenever $xy \neq z$.

By repeating the above reduction, any higher-order function can be reduced to a quadratic one with additional variables: \tilde{f} has **one more variable** and is of **one less degree** than the original function f.

For any minimum-energy value-assignment for the new function, the same assignment of values to the original variables gives the minimum energy to the original function: $(x^*,y^*,w^*,z^*) \in \operatorname*{argmin}_{x,y,w,z\in\mathbb{B}} \tilde{f}(x,y,w,z) \quad \Rightarrow \quad f(x^*,y^*,w^*) = \min_{x,y,w\in\mathbb{B}} f(x,y,w) \; .$

IN2245 - Combinatorial Optimization in Computer Vision

14. Higher-order Clique Reduction – 12 / 36

The problem with reduction by substitution

The first term in

$$Mg(x, y, z) = Mxy - 2Mxz - 2Myz + 3Mz$$

is a quadratic term with a (very) large positive coefficient. According to Theorem 4 in Lecture 2, this makes in all cases the result of reduction non-submodular. It seems such an energy cannot be minimized very well even with QPBO method (see Lecture 8).

Example:

$$f(x_1, x_2, x_3, x_4) = -2x_1x_2 - 3\underbrace{x_2x_3}_{x_5} x_4$$

$$\tilde{f}(x_1, \dots, x_5) = -2x_1x_2 - 3x_5x_4 + Mg(x_2, x_3, x_5)$$

$$= -2x_1x_2 - 3x_4x_5 + 6(x_2x_3 - 2x_2x_5 - 2x_3x_5 + 3x_5)$$

$$= -2x_1x_2 + 6x_2x_3 - 12x_2x_5 - 12x_3x_5 - 3x_4x_5 + 18x_5.$$

IN2245 - Combinatorial Optimization in Computer Vision

14. Higher-order Clique Reduction – 13 / 36

Reduction by minimum selection

Consider a **cubic** pseudo–Boolean function of $x,y,z\in\mathbb{B}$ for $a\in\mathbb{R}$

$$f(x, y, z) = axyz.$$

Observe that

$$xyz = \max_{w \in \mathbb{B}} w(x + y + z - 2) .$$

\boldsymbol{x}	y	z	xyz	x + y + z - 2	$\max_{w \in \mathbb{B}} w(x+y+z-2)$
0	0	0	0	-2	0
0	0	1	0	-1	0
0	1	0	0	-1	0
0	1	1	0	0	0
1	0	0	0	-1	0
1	0	1	0	0	0
1	1	0	0	0	0
1	1	1	1	1	1

IN2245 - Combinatorial Optimization in Computer Vision

14. Higher-order Clique Reduction – 15 / 36

Reduction by minimum selection

Suppose a < 0,

$$axyz = a \max_{w \in \mathbb{B}} w(x+y+z-2) = \min_{w \in \mathbb{B}} aw(x+y+z-2) .$$

Suppose a>0, and let $\bar{x}=1-x$, $\bar{y}=1-y$ and $\bar{z}=1-z$, then

$$\bar{x}\bar{y}\bar{z} = \max_{w \in \mathbb{B}} w(\bar{x} + \bar{y} + \bar{z} - 2) = \max_{w \in \mathbb{B}} w(1 - x + 1 - y + 1 - z - 2)$$
$$= -\min_{w \in \mathbb{B}} w(x + y + z - 1) .$$

Furthermore,

$$\bar{x}\bar{y}\bar{z} = (1-x)(1-y)(1-z) = -(x+y+z) + (xy+xz+yz) - xyz + 1$$
.

Therefore, we obtain

$$axyz = \min_{w \in \mathbb{B}} a(w(x+y+z-1) - (x+y+z) + (xy+xz+yz) + 1)$$
.

IN2245 - Combinatorial Optimization in Computer Vision

14. Higher-order Clique Reduction – 16 / 36

The cubic case

Thus, either case, the cubic term can be replaced by quadratic terms. When axyz appears in a minimization problem with

 \blacksquare a < 0, it can be replaced by

$$aw(x + y + z - 2) = a(wx + wy + wz - 2w)$$
.

 \blacksquare a > 0, it can be replaced by

$$a(w(x+y+z-1)-(x+y+z)+(xy+yz+zx)+1)$$

$$= a(wx + wy + wz + xy + yz + zx - x - y - z - w + 1).$$

Note that this reduction is valid either the function is submodular or not.

IN2245 - Combinatorial Optimization in Computer Vision

14. Higher-order Clique Reduction – 17 / 36

The quartic case

For quartic term axyzt $(x, y, z, t \in \mathbb{B})$, the same trick works if a < 0, that is

$$axyzt = \min_{w \in \mathbb{B}} aw(x+y+z+t-3) .$$

However, if a > 0,

$$\begin{split} \bar{x}\bar{y}\bar{z}\bar{t} &= \max_{w \in \mathbb{B}} w(\bar{x} + \bar{y} + \bar{z} + \bar{t} - 3) \\ &= \max_{w \in \mathbb{B}} w(1 - x + 1 - y + 1 - z + 1 - t - 3) = \max_{w \in \mathbb{B}} w(-x - y - z - t + 1) \;. \end{split}$$

Furthermore.

$$\bar{x}\bar{y}\bar{z}\bar{t} = (1-x)(1-y)(1-z)(1-t)$$

$$= xyzt - (xyz + xyt + xzt + yzt) + (xy + xz + xt + yz + yt + zt)$$

$$- (x+y+z+t) + 1.$$

IN2245 - Combinatorial Optimization in Computer Vision

14. Higher-order Clique Reduction – 18 / 36

The quartic case

Therefore, we obtain

$$\bar{x}\bar{y}\bar{z}\bar{t} = \max_{w \in \mathbb{B}} w(-x - y - z - t + 1) + (xyz + xyt + xzt + yzt)$$

$$-(xy + xz + xt + yz + yt + zt) + (x + y + z + t) - 1.$$

Unlike the cubic case, the maximization problem is not turned into a minimization. Similarly, this does not work with any term of even degree.

In general, for negative higher-order terms the following holds:

$$-x_1 \cdots x_d = \min_{w \in \mathbb{B}} w \left((d-1) - \sum_{i=1}^d x_i \right) .$$

IN2245 - Combinatorial Optimization in Computer Vision

14. Higher-order Clique Reduction – 19 / 36

Symmetric polynomials

A polynomial $p(x_1, x_2, \dots, x_n)$ is said to be symmetric polynomial, if for any permutation π of the subscripts $1, 2, \dots, n$ the following holds

$$p(x_{\pi(1)}, x_{\pi(2)}, \dots, x_{\pi(n)}) = p(x_1, x_2, \dots, x_n)$$
.

That is interchanging any of the variables, one obtain the same polynomial.

IN2245 - Combinatorial Optimization in Computer Vision

14. Higher-order Clique Reduction -20 / 36

Elementary symmetric polynomials

The elementary symmetric polynomials in n variables for $k=0,1,\ldots,n$, are defined by

$$\sigma_0(x_1, x_2, \dots, x_n) = 1 ,$$

$$\sigma_1(x_1, x_2, \dots, x_n) = \sum_{1 \le i \le n} x_i ,$$

$$\sigma_2(x_1, x_2, \dots, x_n) = \sum_{1 \le i < j \le n} x_i x_j ,$$

and so on, ending with

$$\sigma_n(x_1, x_2, \dots, x_n) = x_1 x_2 \cdots x_n .$$

It is known that any symmetric polynomial can be expressed as a polynomial in elementary symmetric polynomials. That is, any symmetric polynomial is given by an expression involving only additions and multiplication of constants and elementary symmetric polynomials.

IN2245 - Combinatorial Optimization in Computer Vision

14. Higher-order Clique Reduction – 21 / 36

The quartic and quintic cases

We would like to generalize the formulæ shown before. Observe that the equations in the cubic case are **symmetric** in the three variables x, y and z.

Therefore, if there exists a generalization for xyzt, the RHS should also be symmetric in the four variables:

$$xyzt = \min_{w \in \mathbb{B}} w(\text{1st order sym.}) + (\text{2nd order sym.})$$
 .

We will write symmetric polynomials as a polynomial of elementary symmetric polynomials. There is only one elementary symmetric polynomial of each degree; the ones we need are:

$$s_0 = 1$$
, $s_1 = x + y + z + t$, $s_2 = xy + yz + zx + tx + ty + tz$.

Since $x, y, z, t \in \mathbb{B}$,

$$s_1^2 = (x+y+z+t)^2 = x+y+z+t+2xy+2yz+2zx+2tx+2ty+2tz = s_1+2s_2$$
.

IN2245 - Combinatorial Optimization in Computer Vision

14. Higher-order Clique Reduction – 22 / 36

The quartic and quintic cases

Therefore, any symmetric polynomial up to second degree, with binary variables, can be written as a linear combination of s_0, s_1 and s_2 . Thus the formula should be of the form for $a, b, c, d, e \in \mathbb{Z}$

$$xyzt = \min_{w \in \mathbb{R}} w(as_1 + b) + (cs_2 + ds_1 + es_0)$$
.

By applying exhaustive search for a, b, c, d and e one can obtain that

$$xyzt = \min_{w \in \mathbb{B}} w(2s_1 + 3) + s_2.$$

One can similarly obtain formula for quintic case. However, the number of auxiliary variables increases. That is

$$xyztu = \min_{(v,w) \in \mathbb{B}} (v(-2r_1+3) + w(-r_1+3)) + r_2$$
,

where r_1 and r_2 are the 1st and 2nd degree elementary symmetric polynomials in x, y, z, t, u.

IN2245 - Combinatorial Optimization in Computer Vision

14. Higher-order Clique Reduction – 23 / 36

Even degree

Theorem 1. Let $x_1, \ldots, x_d \in \mathbb{B}$, where d is even. For a > 0

$$ax_1 \cdots x_d = \min_{w_1, \dots, w_{n_d} \in \mathbb{B}} a \left(\sum_{i=1}^{n_d} w_i (-2\sigma_1 + 4i - 1) \right) + a\sigma_2,$$

where

$$n_d = \left\lfloor rac{d-1}{2}
ight
floor \, , \quad \sigma_1 = \sum_{i=1}^d x_i \; , \quad ext{and} \quad \sigma_2 = \sum_{i=1}^{d-1} \sum_{j=i+1}^d x_i x_j \; .$$

Proof. Suppose that k of the d variables $x_1 = \cdots = x_k = 1$ and the rest are 0. Then, it follows

$$\sigma_1 = k \; , \quad \text{and} \quad \sigma_2 = \frac{\sigma_1^2 - \sigma_1}{2} = \frac{k(k-1)}{2} \; .$$

IN2245 - Combinatorial Optimization in Computer Vision

14. Higher-order Clique Reduction – 24 / 36

Even degree

Proof cont'd. Let $l=\lfloor\frac{k}{2}\rfloor$, $m_d=\lfloor\frac{d-2}{2}\rfloor$, $N=\min(l,m_d)$ and

$$A := \min_{w_1, \dots, w_{n_d} \in \mathbb{B}} \sum_{i=1}^{m_d} w_i (-2\sigma_1 + 4i - 1) + \sigma_2 = \sum_{i=1}^{m_d} \min(0, -2k + 4i - 1) + \sigma_2.$$

- If k is even (k=2l): $-2k+4i-1<0 \Leftrightarrow 4i<4l+1 \Leftrightarrow i \leq l$.
- $\blacksquare \quad \text{If k is odd } \big(k=2l+1\big): \ -2k+4i-1<0 \ \Leftrightarrow \ 4i<4l+3 \ \Leftrightarrow \ i\leqslant l.$

Thus,

$$A = \sum_{i=1}^{N} (-2k + 4i - 1) + \frac{k(k-1)}{2} = 2N^2 - N(2k-1) + \frac{k(k-1)}{2}.$$

Note that if $k \leq d-2$, then

$$l = \left\lfloor \frac{k}{2} \right\rfloor \leqslant \left\lfloor \frac{d-2}{2} \right\rfloor = m_d$$
, hence $N = l$.

IN2245 - Combinatorial Optimization in Computer Vision

14. Higher-order Clique Reduction – 25 / 36

Even degree

Proof cont'd. We know that $A = 2N^2 - N(2k-1) + k(k-1)/2$.

 $\blacksquare \quad k \leqslant d - 2.$

$$k = 2l: A = 2l^2 - l(2 \cdot 2l - 1) + \frac{2l(2l - 1)}{2} = 0.$$

$$k = 2l + 1: A = 2l^2 - l(2(2l + 1) - 1) + \frac{(2l + 1)(2l + 1 - 1)}{2} = 0.$$

 $\blacksquare \quad k=d-1. \text{ Thus, } l=\left\lfloor \frac{k}{2} \right\rfloor = \left\lfloor \frac{d-1}{2} \right\rfloor = \left\lfloor \frac{d-2}{2} \right\rfloor = m_d \text{, and } N=l=m_d.$

$$A = 2m_d^2 - m_d(2(d-1) - 1) + \frac{(d-1)(d-2)}{2}$$
$$= 2m_d^2 - m_d(2(2m_d + 1) - 1) + (2m_d + 1)m_d = 0.$$

$$A = 2(l-1)^{2} - (l-1)(4l-1) + l(2l-1) = 2l^{2} - 4l + 2 - 4l^{2} + 5l - 1 + 2l^{2} - l = 1.$$

Therefore $x_1 \cdots x_d = A$.

IN2245 - Combinatorial Optimization in Computer Vision

14. Higher-order Clique Reduction – 26 / 36

Even degree

Proof cont'd. Since d is even, $n_d = \lfloor \frac{d-1}{2} \rfloor = \lfloor \frac{d-2}{2} \rfloor = m_d$.

$$ax_{1} \cdots x_{d} = aA$$

$$= a \min_{w_{1}, \dots, w_{n_{d}} \in \mathbb{B}} \sum_{i=1}^{m_{d}} w_{i}(-2\sigma_{1} + 4i - 1) + a\sigma_{2}$$

$$= \min_{w_{1}, \dots, w_{n_{d}} \in \mathbb{B}} a \left(\sum_{i=1}^{n_{d}} w_{i}(-2\sigma_{1} + 4i - 1) \right) + a\sigma_{2},$$

which completes the proof in the even-degree case.

IN2245 - Combinatorial Optimization in Computer Vision

14. Higher-order Clique Reduction - 27 / 36

Odd degree

Theorem 2. Let $x_1, \ldots, x_d \in \mathbb{B}$, where d is odd. For a > 0

$$ax_1 \cdots x_d = \min_{w_1, \dots, w_{n_d} \in \mathbb{B}} a \left(\sum_{i=1}^{n_d - 1} w_i (-2\sigma_1 + 4i - 1) + w_{n_d} (-\sigma_1 + 2n_d - 1) \right) + a\sigma_2,$$

where n_d , σ_1 and σ_2 are defined as before.

Proof. We will use the notations defined in the previous proof. When d is odd, then $m_d = \left\lfloor \frac{d-2}{2} \right\rfloor = \left\lfloor \frac{d-1}{2} \right\rfloor - 1 = n_d - 1$. Therefore,

$$\begin{split} & \min_{w_1, \dots, w_{n_d} \in \mathbb{B}} \left(\sum_{i=1}^{n_d-1} w_i (-2\sigma_1 + 4i - 1) + w_{n_d} (-\sigma_1 + 2n_d - 1) \right) + \sigma_2 \\ &= \min_{w_1, \dots, w_{n_d-1} \in \mathbb{B}} \left(\sum_{i=1}^{m_d} w_i (-2\sigma_1 + 4i - 1) \right) + \sigma_2 + \min_{w_{n_d} \in \mathbb{B}} (-\sigma_1 + 2n_d - 1) \\ &= A + \min(0, -\sigma_1 + 2n_d - 1) \; . \end{split}$$

Odd degree

Proof cont'd. Again, suppose that k of the d variables $x_1=\cdots=x_k=1$ and the rest are 0. Since $d=2\left\lfloor\frac{d-1}{2}\right\rfloor+1=2n_d+1$, it follows that

$$-\sigma_1 + 2n_d - 1 = -k + d - 2 \geqslant 0 \quad \Leftrightarrow \quad k \leqslant d - 2.$$

■ $k \leq d-2$. Thus, A=0 and $-\sigma_1+2n_d-1 \geq 0$. Therefore,

$$x_1 \cdots x_d = 0$$
, and $A + \min(0, -\sigma_1 + 2n_d - 1) = 0 + 0 = 0$.

$$A = 2N^{2} - N(2k - 1) + \frac{k(k - 1)}{2} = 2(l - 1)^{2} - (l - 1)(4l - 1) + l(2l - 1) = 1.$$

Therefore, $x_1 \cdots x_d = 0$, and $A + \min(0, -\sigma_1 + 2n_d - 1) = 1 - 1 = 0$.

IN2245 - Combinatorial Optimization in Computer Vision

14. Higher-order Clique Reduction – 29 / 36

Odd degree

Proof cont'd.

 $\blacksquare \quad k = d. \text{ Thus } -\sigma_1 + 2n_d - 1 = -k + 2\left\lfloor \frac{d-1}{2} \right\rfloor - 1 = -k + k - 1 - 1 = -2 \text{ , and } N = m_d = l - 1 \text{, } k = 2l + 1 \text{, thus } l = l - 1 \text{, } l = 2l + 1 \text{, thus } l = l - 1 \text{, } l = 2l + 1 \text{, } l = 2l + 1 \text{, } l = 2l + 2 \text{, } l = 2l + 2$

$$A = 2N^{2} - N(2k - 1) + \frac{k(k - 1)}{2} = 2(l - 1)^{2} - (l - 1)(4l + 1) + (2l + 1)l = 3;$$

Therefore $x_1 \cdots x_d = 1$ and $A + \min(0, -\sigma_1 + 2n_d - 1) = 3 - 2 = 1$.

As we have seen (in the reduction by minimization),

$$axyz = \min_{w \in \mathbb{B}} a(w(x+y+z-1) - (x+y+z) + (xy+yz+zx) + 1).$$

However, by applying the theorem, we obtain

$$= \min_{w_1 \in \mathbb{B}} aw_1 \left(-(x+y+z-1) + 1 \right) + a(xy+yz+zx) .$$

IN2245 - Combinatorial Optimization in Computer Vision

14. Higher-order Clique Reduction – 30 / 36

General case

Consider a monomial $ax_1 \cdots x_d$ of degree d. We define the elementary symmetric polynomials in these variables as

$$\sigma_1 = \sum_{i=1}^d x_i \;, \quad ext{and} \quad \sigma_2 = \sum_{i=1}^{d-1} \sum_{j=i+1}^d x_i x_j = rac{\sigma_1(\sigma_1-1)}{2} \;.$$

In summary,

- $\blacksquare \quad \text{If } a < 0: \ ax_1 \cdots x_d = \min_{w \in \mathbb{R}} aw(\sigma_1 (d-1)).$
- If a > 0:

$$ax_1 \cdots x_d = a \min_{w_1, \dots, w_{n_d} \in \mathbb{B}} \sum_{i=1}^{n_d} w_i (c_{i,d}(-\sigma_1 + 2i) - 1) + a\sigma_2$$

where

$$n_d = \left\lfloor rac{d-1}{2}
ight
floor \, , \quad c_{i,d} = egin{cases} 1, & ext{if } d ext{ is odd and } i = n_d, \ 2, & ext{otherwise}. \end{cases}$$

General case

- Any pseudo-Boolean function can be uniquely written as a polynomial in binary variables.
- Each monomial can be reduced to a quadratic polynomial by making use of the above technique.

Therefore, the whole function can be reduced to a quadratic polynomial, such that if any assignment of values to the variables in the reduced polynomial achieves its minimum, the assignment restricted to the original variables achieves a minimum of the original function.

Note that the reduction is valid either the function is submodular or not.

The number of additional variables (per clique) in the worst case is exponential in d. For instance, with a clique of size five, there can be up to one quintic, five quartic, and ten cubic terms, and 17 new variables could be needed.

Transforming multi-label functions

Let $\mathcal V$ and $\mathcal L$ be the set of pixels and labels, respectively. Consider the following energy function on a labeling $\mathbf y \in \mathcal Y = \mathcal Y_1 \times \cdots \times \mathcal Y_{|\mathcal V|} = \mathcal L^{\mathcal V}$

$$E(\mathbf{y}) = \sum_{c \in \mathcal{C}} E_c(y_c) \;,$$

where C is the set of cliques and $E_c(y_c)$ denotes the local energy depending on the labels $y_c \in \mathcal{L}^c$.

The goal: is to optimize higher-order energies with more than two labels.

One can apply fusion move (see Lecture 13.), where in each iteration the current labeling and a proposed one is fused by minimizing a pseudo-Boolean energy.

For a **proposed labeling** $\mathbf{p} \in \mathcal{Y}$, we consider a binary labeling $\mathbf{z} \in \mathbb{B}^{\mathcal{V}}$ such that for all $v \in \mathcal{V}$

$$y'_v = \begin{cases} y_v, & \text{if } z_v = 0\\ p_v, & \text{if } z_v = 1 \end{cases}.$$

14. Higher-order Clique Reduction – 34 / 36

Transforming multi-label functions

Therefore,

$$y_v' = (1 - z_v)y_v + z_v p_v.$$

We define a pseudo-Boolean function

$$y'_v = (1 - z_v)y_v + z_v p_v .$$

$$f(\mathbf{z}) = \sum_{c \in \mathcal{C}} E_c (\lambda_c(z_c; y_c, p_c)) ,$$

where for all $c \in \mathcal{C}$,

$$(\lambda_c(z_c; y_c, p_c))_v = y_v' \quad \forall v \in c.$$

- 1. The polynomial $f(\mathbf{z})$ is reduced into a quadratic one.
- 2. The QPBO method (see Lecture 8.) can be used to minimize $f(\mathbf{z})$, and it results an assignment of 0,1, or -1 to each pixel v.
- 3. y_v is updated to p_v if 1 is assigned to v, otherwise it remains unchanged.
- 4. Iterate the process until some convergence criterion is met.
